

# Glass-Ceramic Materials: Liquid Phase Separation, Nucleation and Crystallization in Glasses (Glass Science and Technology)

Glass-ceramic materials are new, solid substances that are especially useful because of their exceptional technical parameters, including a wide range of unusual combinations of properties. The characteristics of glass-ceramic materials basically depend on the properties of the finely separated crystalline phase and the residual glass phase which make up the glass-ceramic material. The kind of crystalline phase and thus also the final properties of the glass-ceramic material can be controlled by the initial glass composition and by its heat treatment. In this way, an almost unlimited number of types of glass-ceramic material can be prepared with various combinations of properties, many of which are useful in practice. The production of glass-ceramic materials is becoming a new field of material technology, based on special manufacturing processes, especially controlled crystallization of glasses based on theoretical knowledge, primarily in the field of phase transformation in condensed systems and the physics of solid substances.
