

Signaling PHP: Catching Signals in PHP CLI Scripts

PHP has grown from its web roots. You've been working with PHP for a while and have watched it grow from its roots as a simple templating language to powering some of the largest sites in the world. Facebook. Wikipedia. WordPress. You've started creating more complicated applications that now need some work done other than displaying content to the screen. You want to leverage your PHP knowledge to create tools to let you get things done. Server-level programming can be a pain. Deployment scripts, database migrations, asset minification, queue workers, these are all things you need to worry about in modern web applications. There's information out there on how to accomplish these tasks with PHP, but what you really want is one reference guide to show you how to do it at the lowest levels.

You need a foundation in using it on the CLI to respond to OS level signals. PHP gives you the opportunity to leverage your existing skills and libraries in new ways. One of the things you will want to do when building CLI scripts is respond to OS level signals. Everything from KILL to the user-defined USR signals are available to you to trap and branch your code as necessary. While PHP was built for the web, it has grown into a tool that can do so much more. Signaling PHP is your gateway into understanding how PHP interacts with operating systems. Why not use the most popular language on the web to creating tools on the server?
